DOI: 10.3247/SL4nmr11.003

Presented at *6th BFF on Magnetic Resonance Microsystem*,  
Saig/Titisee (Freiburg), Germany, 26-29 July 2011

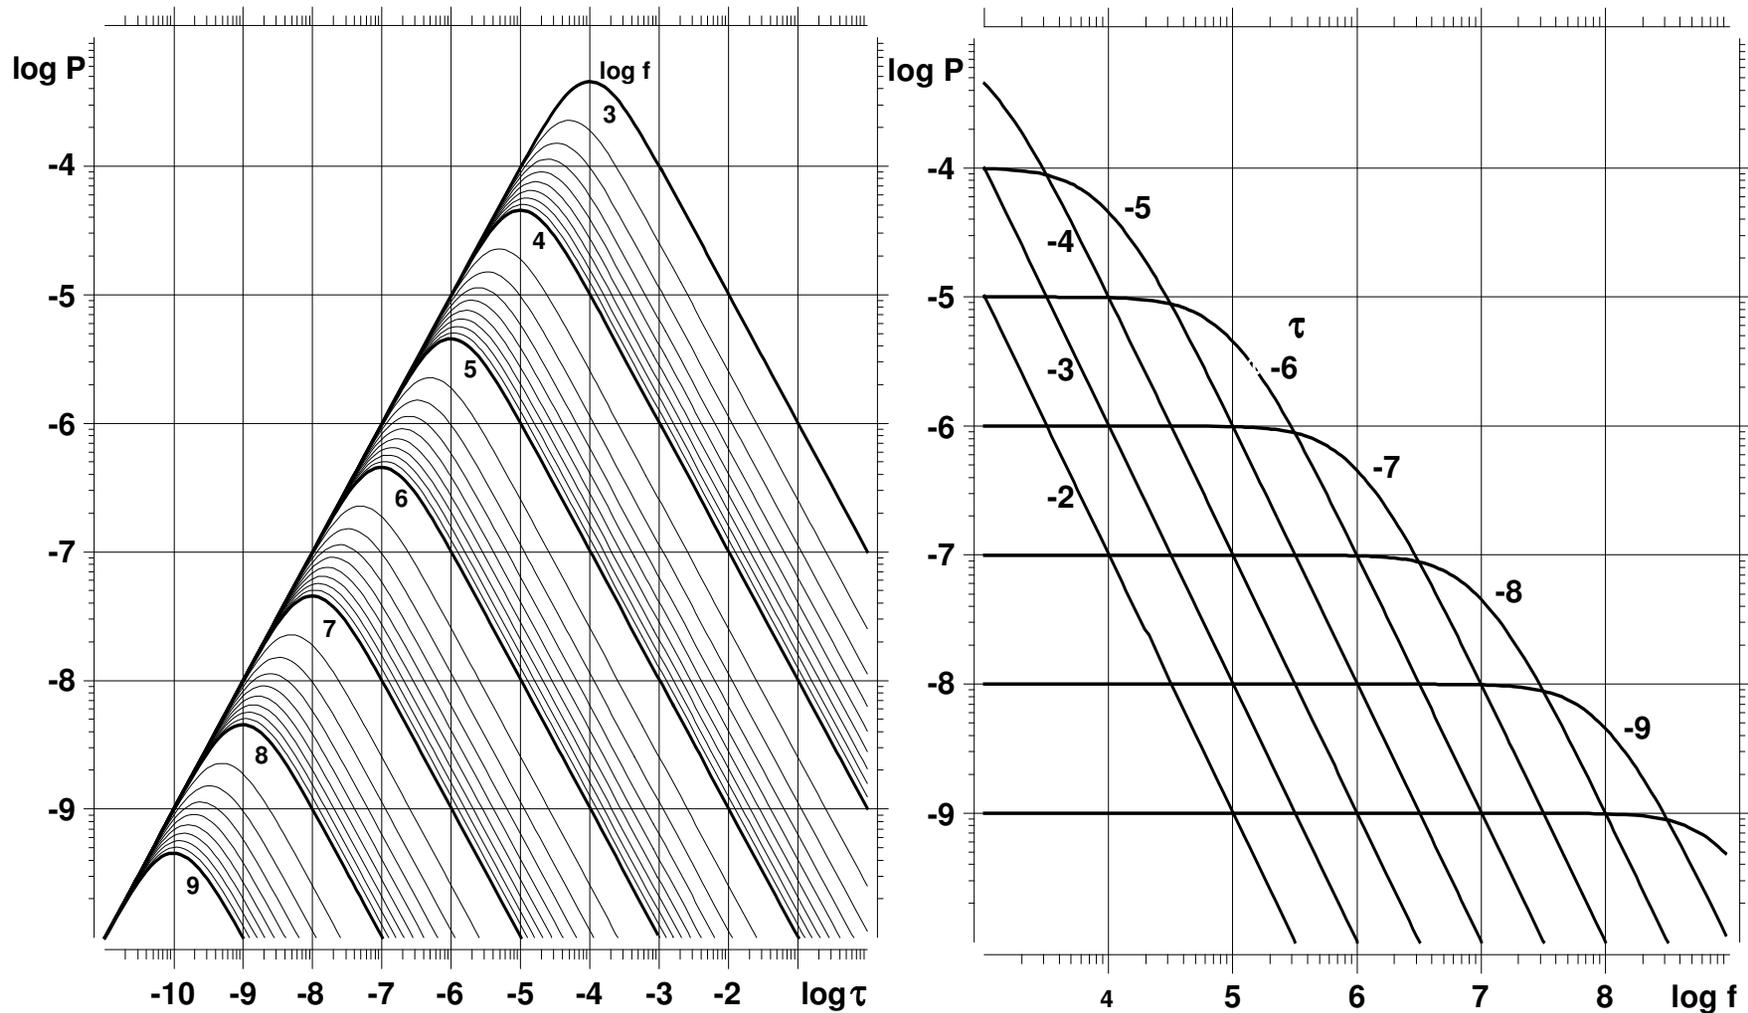

# The purpose of this talk is ... to raise doubts ☹ so we can discuss them

## Topics to be discussed:

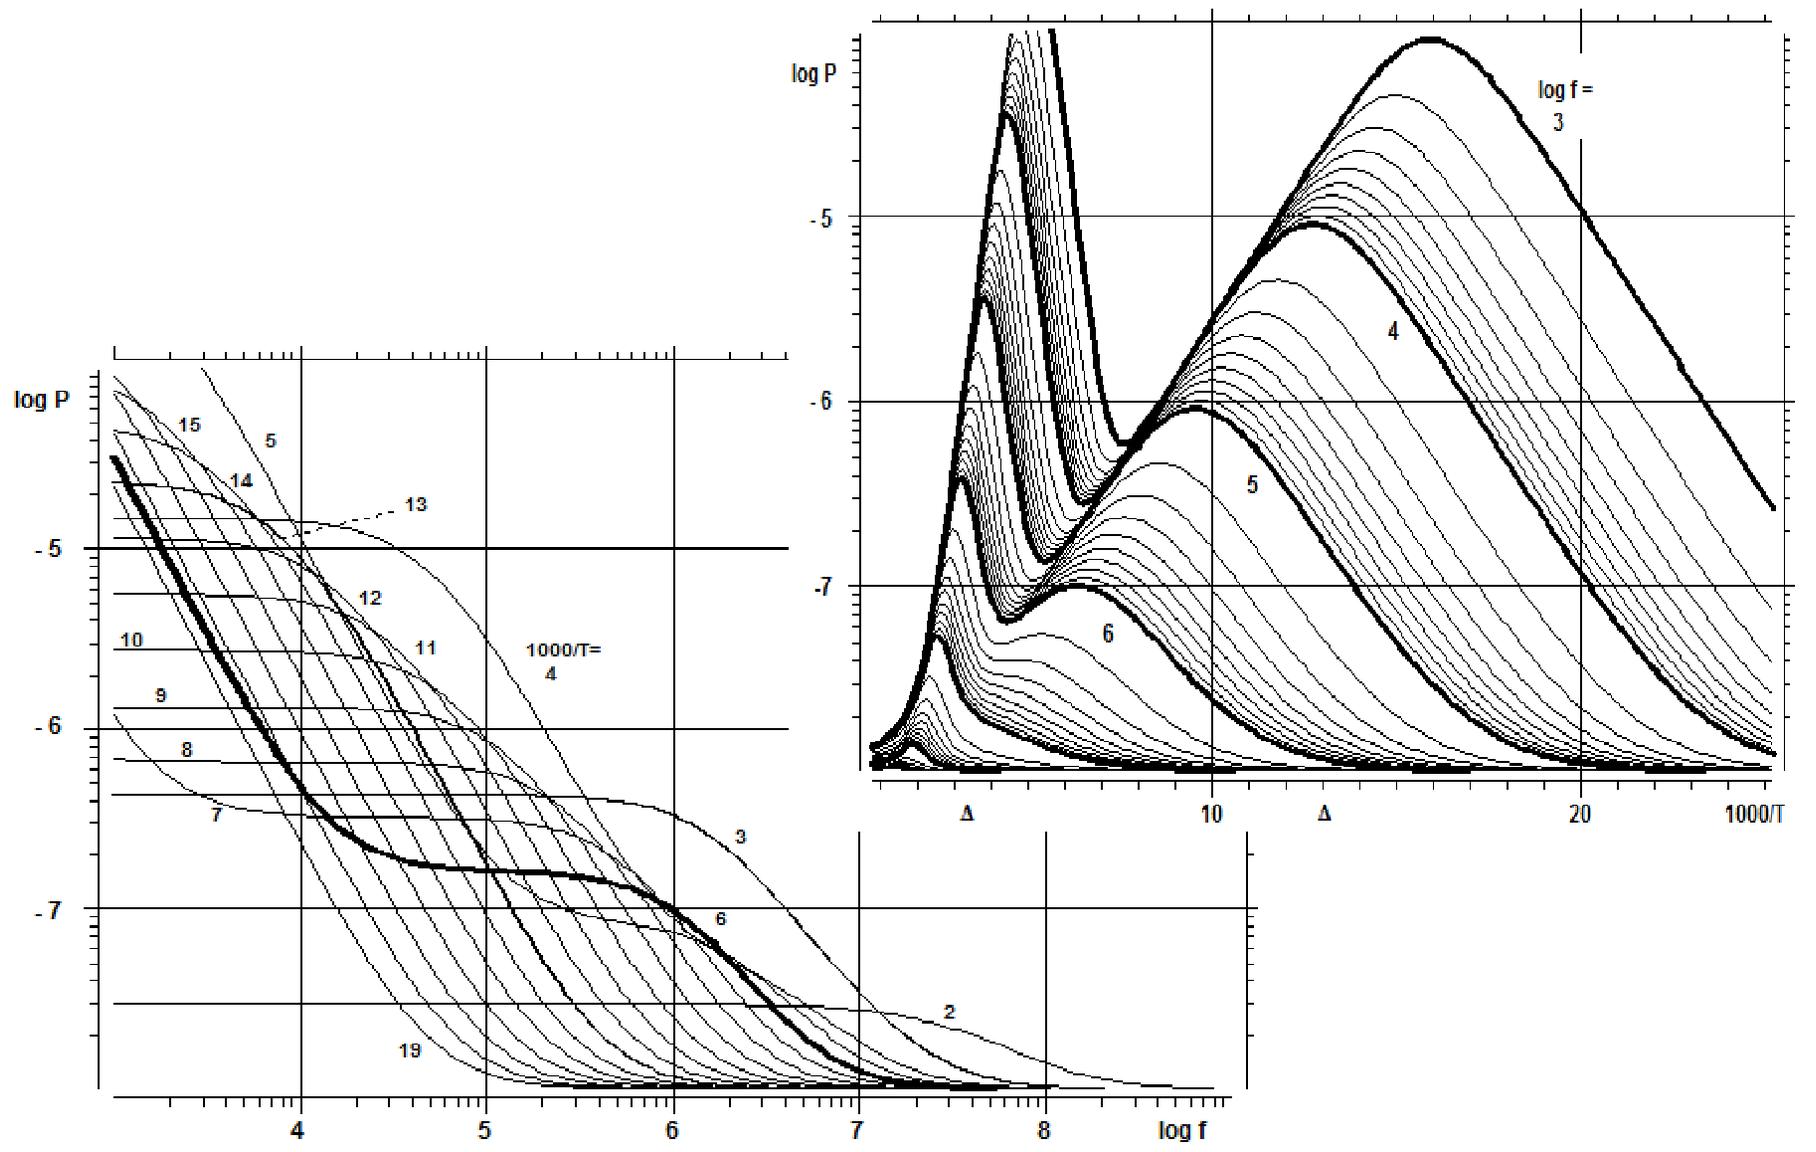

- Relaxation as an ensemble-enabling process (thermo-dynamics)
- The role of relaxation in establishing nuclear magnetic [thermal] polarization
- Relaxation and phase coherence of quantum spin states
- Relaxation and the feasibility of a single-spin experiment
- Relaxation and the concept of “spontaneous” emission
- **Time-dependent Hamiltonians, averaging, and the nature of quantum transitions**
- **Is an FID a superposition of *instantaneous* transitions or of *lengthy* ones?**
- Comparing CW and pulsed NMR in the limit of very long relaxation times
- Relaxation via coil-induced magnetic field fluctuations Relaxation and S/N ratio

# What I am not going to talk about: BPP formula

Function  $P(\tau, f) = J_\tau(\omega) + 4 J_\tau(2\omega)$ , where  $J_\tau(\omega) = 2\tau/[1+(\omega\tau)^2]$  and  $\omega = 2\pi f$

# What I will skip: BPP+Arrhenius processes

# What I will also barely mention: Relaxation Mechanisms (heat & entropy “pumps”)

## Spin interactions:

- Nucleus - Nucleus Dipole-Dipole
- Nuclear - Electron Dipole-Dipole
- Chemical spin anisotropy
- Quadrupole
- Spin-Rotation
- ...

N different types

## Molecular dynamics:

- Rotational diffusion
- Translational diffusion
- Internal rotations
- Librations
- Reptations
- ...

M different types

**Total:**  $N \times M$  principal formulas  
plus  $(N \times M) (N \times M - 1) / 2$  cross-relaxation ones

Example: for  $N = 5$ ,  $M = 5$  we have 25 principal and 300 cross “kinds of pumps”

## For what I want to say

we just need to keep in mind that relaxations reflect large numbers of interactions *among* spins, as well as *between spins and the rest of the world*, which

- (a) are time-dependent,
- (b) fluctuate too fast for the system to follow,
- (c) and time-average to zero

Let us call them simply *relaxation interactions*

They do not appear in the static Hamiltonian, yet they are paramount to understanding the NMR phenomenon

# Relaxation – like interactions as an ensemble-enabling process

Thermodynamics is *enabled* by relaxations

Without relaxation there would be **NO thermal equilibrium,**

... and **NO thermal polarization**

... and **NO signal !**

(or not ?)

# Relaxation and phase-coherence of spin states

**Relaxation destroys induced phase coherence ...**

(decay of an FID in even a perfectly homogeneous field)

**... but it also ...**

induces a degree of **spontaneous** phase coherence

(consider the spin noise phenomenon)

# Relaxation phenomena in quantum systems

The density matrix of the spin system is a *projection* of a density matrix defined in a much larger Liouville-space onto a subspace thereof

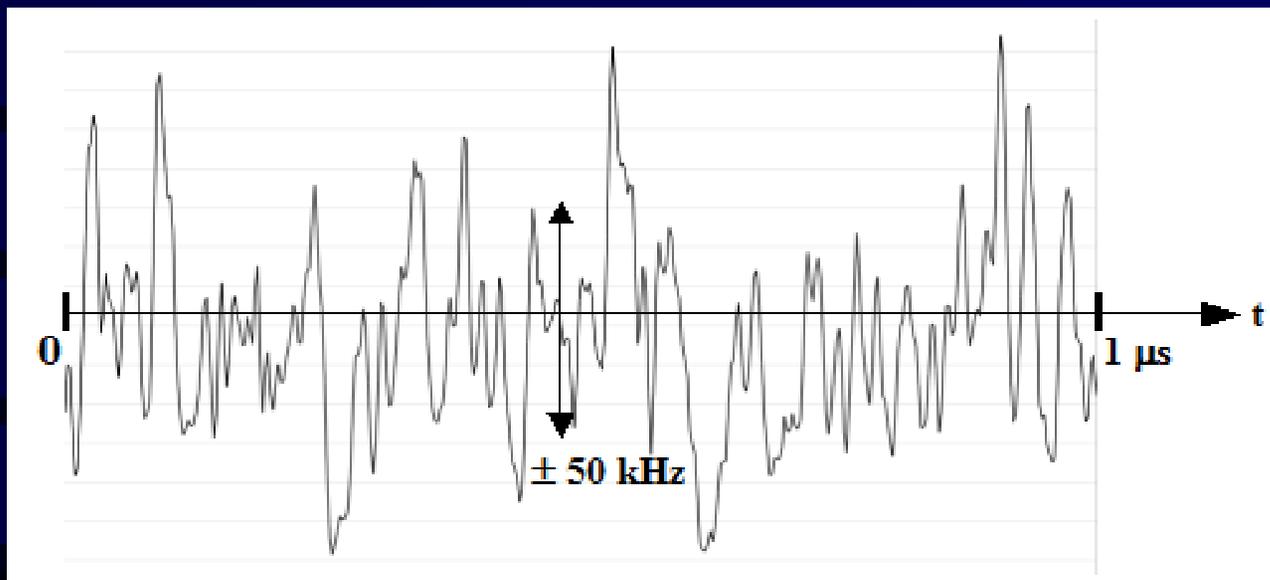

## Principal effects of relaxation interactions:

- ✓ Broadening of quantum energy levels
- ✓ Finite lifetimes of quantum eigenstates
- ✓ Appearance of 'spontaneous' emissions
- ✓ Broadening of spectral lines
- ✓ 'Forbidden' coherences

**None of these concepts is applicable to an 'isolated spin system'**

## But let us have a look at one such interaction

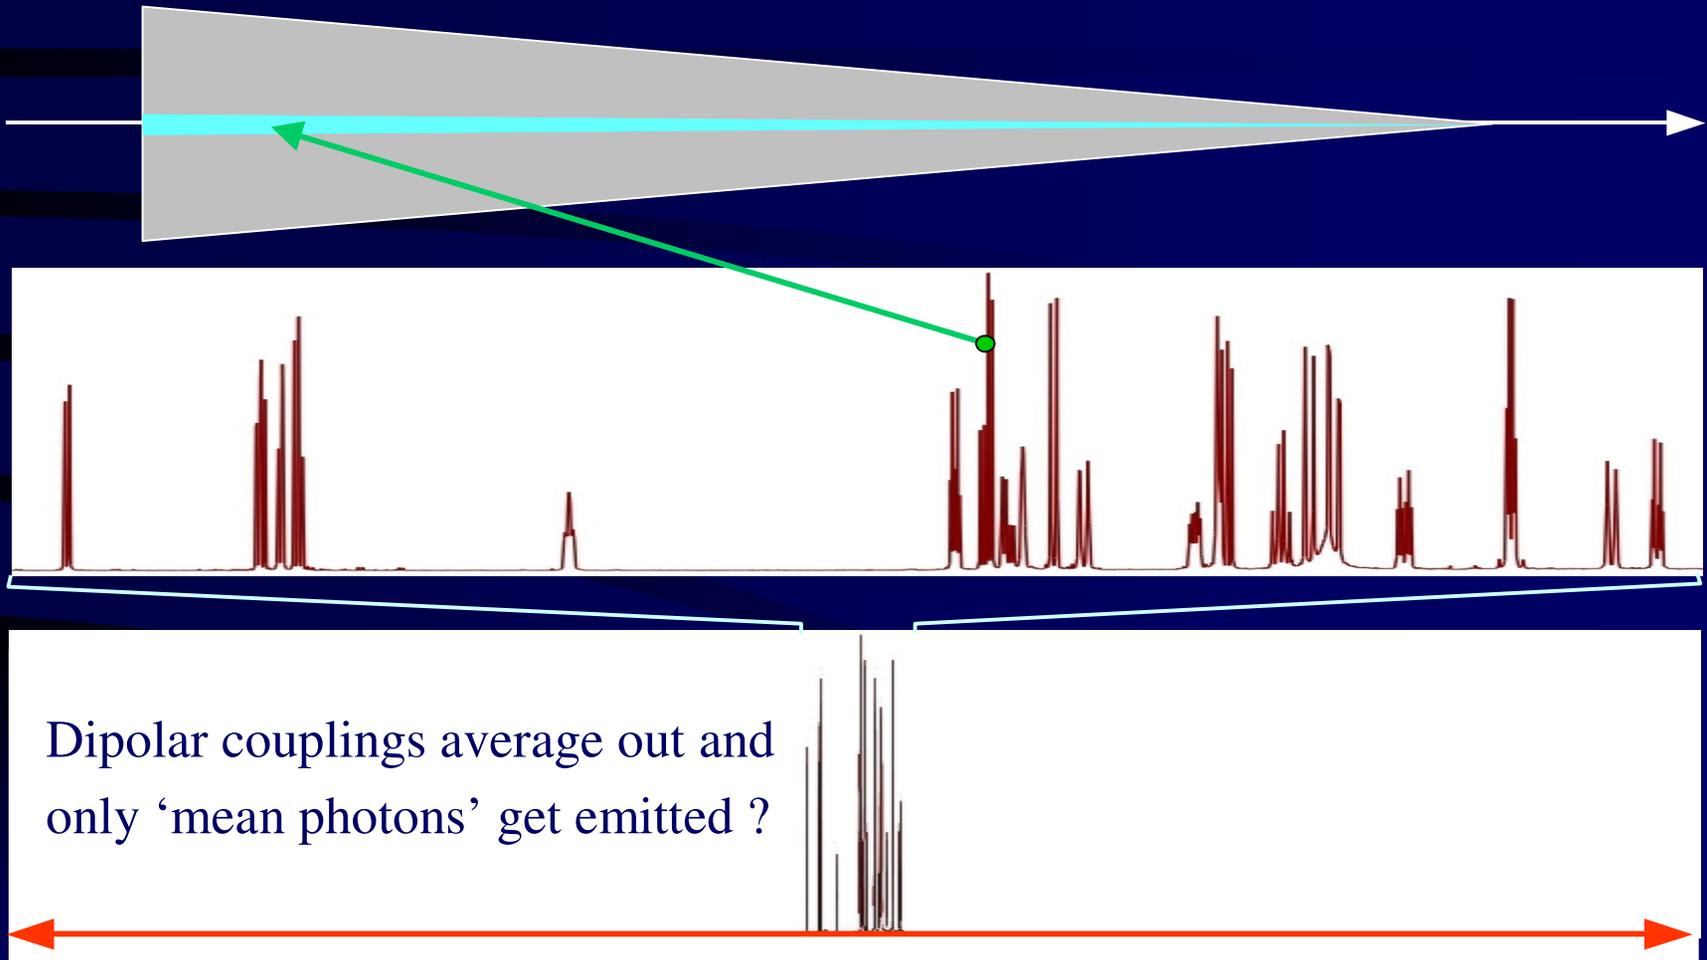

Dipolar interaction between vicinal protons of a methylene group under typical conditions of a small-molecule liquid-state NMR:

The molecular tumbling averages it out to about 0.01 Hz

To achieve this, a random walk brownian motion needs hundreds of seconds – the whole duration of an FID !

# FID's of time-averaged quantum systems: a mind-boggling puzzle

Dipolar couplings average out and  
only 'mean photons' get emitted ?

## So what really IS an FID?

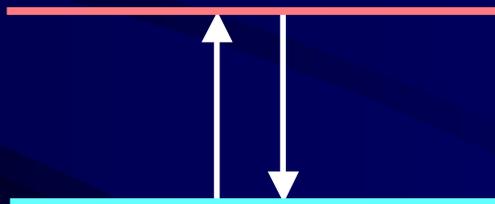

- ? A *swarm of brief, pulse-like* quantum transitions
- ? A *sum of many long* quantum transitions
- ? **Something else altogether**

# Transitions in Quantum Physics?

Consider this simple fact:

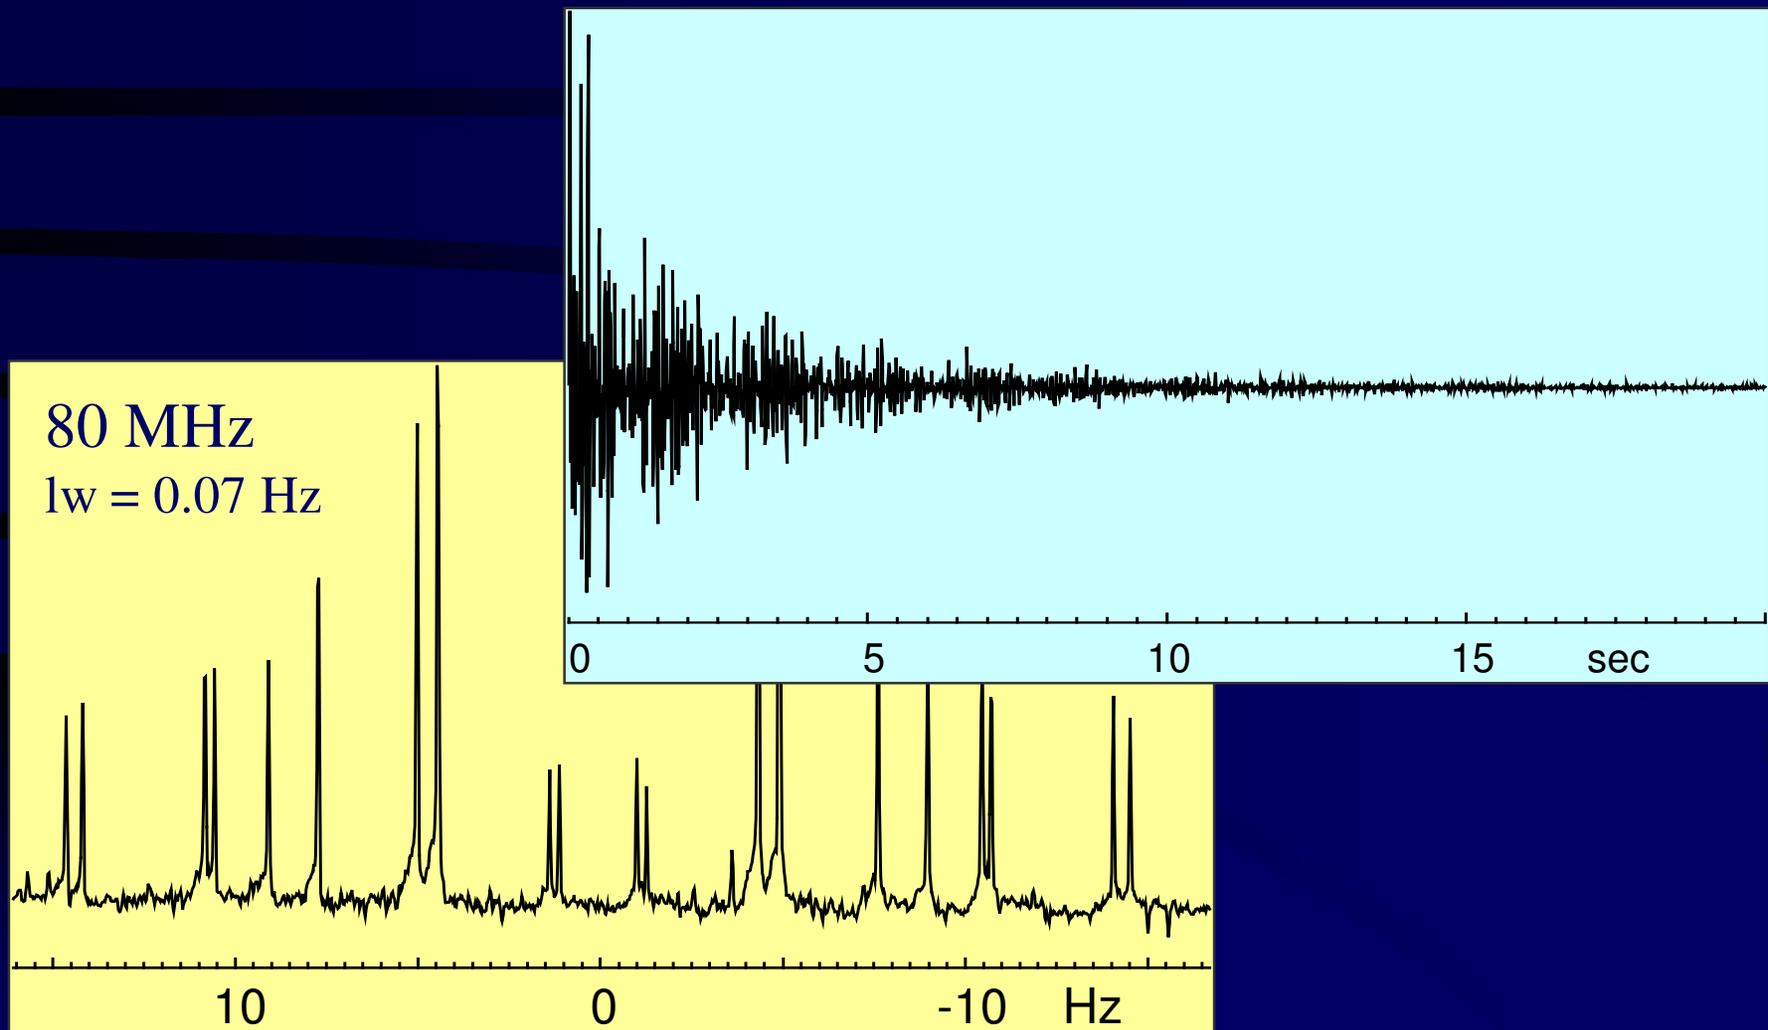

Quantum Physics has NO apparatus to tell us what happens during a Quantum Transition!

By *convention*, and *convention* only, transitions are assumed to be instantaneous.

# Quantum transitions lasting 15 seconds !?

Why not! Quantum Physics can't contradict it

## So how can we describe an FID?

I presently believe that it is best done (at least for practical purposes) as a smooth, transition-less evolution in the Liouville-space of the combined {spin-system-cum-coil} under the effect of its time-averaged Hamiltonian (including the spins-coil coupling) and the relaxation interactions with their second-order secular effects.

Nothing less can do it!

Alas, it still does not cover the radiation component  
(if really present)

**Thank you – and let's Discuss!**
